Received January 15, 2015

We investigate the bifurcation phenomena in a Belousov–Zhabotinsky reaction model by applying Hopf bifurcation theory in frequency domain and harmonic balance method. The high accurate predictions, i.e. fourth-order harmonic balance approximation, on frequencies, amplitudes, and approximation expressions for periodic solutions emerging from Hopf bifurcation are provided. We also detect the stability and location of these periodic solutions. Numerical simulations not only confirm the theoretical analysis results but also illustrate some complex oscillations such as a cascade of period-doubling bifurcation, quasi-periodic solution, and period-doubling route to chaos. All these results improve the understanding of the dynamics of the model.

Keywords: Belousov–Zhabotinsky reaction; frequency domain; fourth-order harmonic balance.

1. Introduction

Belousov–Zhabotinsky (BZ) reaction is a family of chemical oscillation reaction, which is the oxidation and bromination of an organic compound [Györgyi & Field, 1991]. It is well known for its rich and complex oscillations. A great deal of experimental and numerical simulation studies suggest that BZ reaction can exhibit various types of oscillations.
and complex dynamics, such as heterogeneous oscillation [Kulnet, 1986], spiral waves [Keener & Tyson, 1986], period-doubling cascade [Györgyi & Field, 1991], deterministic chaos [Zhang et al., 1993], chemical turbulence [Zhou & Yang, 2000], hyperchaos [Li et al., 2002a], mesoscopic dynamical behavior [Li & Zhou, 2004], breathing front dynamics [Marts et al., 2004], coexistence of two bifurcation regimes [Wang et al., 2005], period-doubling and chaotic oscillations [Zong et al., 2007], chaotic bursters [Bi, 2010]. In addition, Dolzmann et al. [2007] reported complex optical behavior in a nonstationary ferroin catalyzed BZ reaction. Guo et al. [2014] studied the dynamical behavior in the spatial-temporal domain for a BZ reaction by using a spatial-temporal domain identification and frequency domain analysis approach.

A large number of mathematical models have been developed to describe the BZ reaction in detail. The models proposed by Györgyi and Field [1991, 1992] have attracted a great deal of attention from researchers in different fields [Li et al., 2002b; Zong et al., 2007; Freire et al., 2009; Li & Chang, 2012; Li, 2012]. In 1991, Györgyi et al. [1991] proposed a 11-variable BZ reaction model in a well-mixed, continuous-flow, stirred tank reactor (CSTR). Although this model can reproduce the behaviors experimentally observed at low CSTR flow rates, it is difficult to analyze the dynamical structure of the system. Then, the authors [Györgyi & Field, 1991] simplified the 11-variable model to a 7-variable model, and the 7-variable model was further reduced to two 4-variable models and one 3-variable model. Complex oscillations and chaotic dynamics in the 4-variable models are consistent with those experimentally observed at both high and low CSTR flow rates. Some studies of dynamical behaviors in one of 4-variable models, model D_{EQ}, have been reported. Györgyi and Field [1991] numerically showed complex oscillations in this model including periodic window, a cascade of period-doubling and chaos at low flow rates, complex limit cycles and chaos at high flow rates. Li et al. [2002b] studied chaos synchronization at low flow rate. Zong et al. [2007] experimentally and numerically investigated dynamical behaviors at high flow rate, and they found some complex oscillations such as mixed-mode oscillation at low flow rate, periodic-doubling oscillation and chaos at high flow rate. Li and Chang [2012] theoretically analyzed Hopf bifurcation in time domain at both low and high flow rates. By applying Hopf bifurcation theory in frequency domain and second-order harmonic balance method, Li [2012] provided the estimates of frequencies and amplitudes, the explicit approximation expressions for the periodic oscillations emerging from Hopf bifurcation.

In this work, we further study the bifurcations in this 4-variable BZ reaction model D_{EQ}. By using Hopf bifurcation theorem in frequency domain [Mees & Chua, 1979; Moiola & Chen, 1996], we theoretically analyze Hopf bifurcation of the model. We provide higher accurate predictions on frequencies, amplitudes, and explicit formulas of periodic solutions arising from Hopf bifurcation by applying fourth-order harmonic balance method [Mees, 1981; Moiola et al., 1991; Moiola & Chen, 1993, 1996]. The stability and location of these periodic solutions are also detected. In addition, we investigate the bifurcations of periodic orbit emerging from Hopf bifurcation. Furthermore, our numerical simulations show some new system behaviors including torus bifurcation at both low and high flow rates, period-doubling bifurcation, a cascade of period-doubling bifurcation and period-doubling route to chaos at high flow rate. All these results help to understand the dynamics of the BZ reaction.

The rest of article is organized as follows: In Sec. 2, we analyze the existence of Hopf bifurcation in frequency domain. In Sec. 3, the frequencies, amplitudes of periodic solutions generated from Hopf bifurcation and their explicit expressions are presented by fourth-order harmonic balance method. We also detect the stability and location of these periodic solutions. Numerical simulations are shown in Sec. 4 to verify the theoretical analysis results and display the complex dynamics. Section 5 contains the conclusions.

2. Equilibrium Points and Bifurcations

2.1. BZ reaction model

Consider the following BZ model.
Bifurcation Analysis of a Belousov–Zhabotinsky Reaction Model

\[
\begin{align*}
\frac{d[Br^-]}{dt} &= -k_{D4}[H^+][Br^-][HBrO_2] - k_{D2}[BrO_3^-][H^+]^2[Br^-] + k_{D7}[Ce(IV)][BrMA] \\
&\quad + k_{D8}[MA]_{QSS}[BrMA] + k_f([Br^-]_{mf} - [Br^-]) \\
\frac{d[HBrO_2]}{dt} &= -k_{D4}[H^+]^2[Br^-][HBrO_2] + k_{D2}[BrO_3^-][H^+]^2[Br^-] - 2k_{D3}[HBrO_2]^2 \\
&\quad + 0.5k_{D4}[H^+][Ce]_{(IV)}/[BrO_2]_{EQ} - 0.5k_{D4}[HBrO_2][Ce(IV)] \\
&\quad + k_f([HBrO_2]_{mf} - [HBrO_2]) \\
\frac{d[Ce(IV)]}{dt} &= k_{D4}[H^+]^2[Ce]_{(IV)}/[BrO_2]_{EQ} - k_{D5}[HBrO_2][Ce(IV)] - k_{D6}[MA]_{(IV)} - k_{D7}[Ce(IV)] \\
\frac{d[BrMA]}{dt} &= 2k_{D4}[H^+]^2[Br^-][HBrO_2] + k_{D5}[BrO_3^-][H^+]^2[Br^-] + k_{D3}[HBrO_2]^2 \\
&\quad - k_{D7}[Ce(IV)][BrMA] - k_{D8}[MA]_{QSS} + k_f([BrMA]_{mf} - [BrMA]),
\end{align*}
\]

where

- \([MA]_{QSS} = -k_{C10}[BrMA] + \frac{(k_{C10}[BrMA])^2 + 8k_{C11}k_{C11}[Ce(IV)]}{4k_{C11}}\)
- \([BrO_2]_{EQ} = \sqrt{\frac{k_{C4}[HBrO_2]}{k_{C7}}}\)
- \([Ce]_{(IV)} = [Ce(III)]_{mf}\).

\([\cdot]_{mf}\) refers to the mixed-feed concentration of the component, which is assumed to be zero for state variables [Gyorgyi & Field, 1991]. The four state variables in this model are the concentrations of bromide ion \([Br^-]\), bromous acid \([HBrO_2]\), cerium ion \([Ce(IV)\), and bromalonic acid \([BrMA]\). \([H^+]\) and \([BrO_3^-]\) are hydrogen ion and bromate ion, respectively. \([MA]\) is malonic acid. The parameter \(k_f\) represents CSTR flow rate. The parameters \(k_{Dj}\) \((j = 1, \ldots, 8)\) and \(k_{Cj}\) \((j = 4, 5, 8, 10, 11)\) are constants, and their meanings can be found in [Gyorgyi & Field, 1991].

In this work, we further investigate bifurcations in BZ reaction model (1). The flow rate \(k_f\) is taken as bifurcation parameter, and other parameter values are chosen to be:

- \([BrO_2^-] = 0.1\ M, \quad [H^+] = 0.38\ M, \quad [MA] = 0.25\ M, \quad [Ce(III)] = 8.33 \times 10^{-4}\ M, \quad k_{D1} = 2 \times 10^6\ M^{-2}s^{-1}, \quad k_{D2} = 2.0\ M^{-3}s^{-1}, \quad k_{D3} = 3 \times 10^4\ M^{-1}s^{-1}, \quad k_{D4} = 6.2 \times 10^4\ M^{-2}s^{-1}, \quad k_{D5} = 7 \times 10^3\ M^{-1}s^{-1}, \quad k_{D6} = 0.3\ M^{-1}s^{-1}, \quad k_{D7} = 30\ M^{-1}s^{-1}, \quad k_{D8} = 2.4 \times 10^4\ M^{-1}s^{-1}, \quad k_{C4} = 0.858s^{-1}, \quad k_{C5} = 4.2 \times 10^3\ M^{-1}s^{-1}, \quad k_{C6} = 0.3\ [MA]s^{-1}, \quad k_{C7} = 2.4 \times 10^4\ M^{-1}s^{-1}, \quad k_{C8} = 3 \times 10^3\ M^{-1}s^{-1}. \)

According to [Wiggins, 1990], simple qualitative analysis gives the following conclusion:

**Conclusion 1**

- For \(2 \times 10^{-4} < k_f < 6.05172 \times 10^{-4}\) and \(1.54738 \times 10^{-3} < k_f < 3.0 \times 10^{-2}\), system (1) has a stable node;
For $6.05172 \times 10^{-4} < k_f < 1.54738 \times 10^{-3}$, system (1) has an unstable node.

For $k_f^2 = 6.05172 \times 10^{-4}$ and $k_f^2 = 1.54738 \times 10^{-3}$, system (1) has two nonhyperbolic equilibrium points with a single pair of pure imaginary eigenvalues.

Chen, 1996, model (1) is rewritten in the following form:

$$\dot{x} = A(k)x + By(g)$$

(2)

together with a second output equation

$$y = e = -Cx,$$

(3)

2.2. Hopf bifurcation for equilibrium point in frequency domain

In order to apply Hopf bifurcation theorem in frequency domain [Mees & Chua, 1979; Moiola & Chen, 1996], model (1) is rewritten in the following form:

$$A(k) = \begin{pmatrix}
-0.02888 - k & 0 & 0 & 0 \\
0.02888 & -k & 0 & 0 \\
0 & 0 & -0.075 - k & 0 \\
0.02888 & 0 & 0 & -k \\
\end{pmatrix},
B = \begin{pmatrix}
1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1 \\
\end{pmatrix},
$$

where

$$x = ([\text{Br}^-], [\text{HBrO}_2], [\text{Ce(IV)}], [\text{BrMA}])^T,$$

$$k = k_f, \quad e = (e_1, e_2, e_3, e_4)^T,$$

$$g(y) = (g_1, g_2, g_3, g_4)^T.$$

Taking Laplace transforms on both sides of Eq. (2), we can separate Eq. (2) into a linear part with a transfer function

$$G(s; k) = C(sI - A(k))^{-1}B$$

and a memoryless nonlinear part

$$u \triangleq g(e) \triangleq g(y).$$

(5)

It can be shown that systems (2) and (3) are equivalent to the feedback systems (4) and (5), where $s$ is the Laplace variable, and the solution $\hat{e}$ of $G(0; k)g(e) + e = 0$, i.e. the equilibrium point $\hat{e}$ for systems (4) and (5), is equivalent to the equilibrium point $\hat{x}$ in Eq. (2) [Mees & Chua, 1979].

$$F(\lambda, s, k) = \det(\lambda I - G(s; k)D_1).$$

(6)
According to Hopf bifurcation theory in frequency domain [Mees & Chua, 1979; Moiola & Chen, 1996], Hopf bifurcation can occur at an equilibrium point \( \hat{\epsilon} \) for \( k = k_0 \) provided that two conditions are satisfied: (1) \( F(\lambda, s, k) = 0 \) has a single root \( \lambda(\omega_0) = -1 + i\omega_0 \) when \( k = k_0, s = \omega_0 \), where \( \omega_0 \) is the pure imaginary eigenvalue of equilibrium point \( \hat{\epsilon} \) equivalent to \( \hat{\epsilon} \), of model (2) at \( k = k_0 \); (2) \( \frac{\partial F(\lambda, s, k)}{\partial \lambda}(\theta, \omega, s) \) and \( \frac{\partial F(\lambda, s, k)}{\partial \omega}(\theta, \omega, s) \) are nonzero and not parallel.

Calculations show that systems (4) and (5) have two special equilibrium points:

(a) \( \dot{\epsilon}_1 = (-3.13748866 \times 10^{-6}, -3.914231394 \times 10^{-7}, -1.385673176 \times 10^{-5}, -1.539902738 \times 10^{-1}) \) at \( k_01 = 6.05172 \times 10^{-4} \), with a single eigenvalue \( \lambda(\omega_0) = -1 + i\omega_0 \), \( \omega_01 = 8.157976072 \times 10^{-2} \), \( \frac{\partial F(\lambda, s, k)}{\partial \lambda}(\theta, \omega, s) \) and \( \frac{\partial F(\lambda, s, k)}{\partial \omega}(\theta, \omega, s) \) are nonzero and not parallel.

(b) \( \dot{\epsilon}_2 = (-7.259248677 \times 10^{-7}, -3.71716701 \times 10^{-6}, -3.614864477 \times 10^{-5}, -1.34935985 \times 10^{-1}) \) at \( k_02 = 1.54738 \times 10^{-3} \), with a single eigenvalue \( \lambda(\omega_0) = -1 + i\omega_0 \), \( \omega_02 = 6.15181694142 \times 10^{-2} \), \( \frac{\partial F(\lambda, s, k)}{\partial \lambda}(\theta, \omega, s) \) and \( \frac{\partial F(\lambda, s, k)}{\partial \omega}(\theta, \omega, s) \) are nonzero and not parallel.

Therefore, we have the following result:

**Conclusion 2.** For feedback systems (4) and (5), two Hopf bifurcations HB\(^1\) and HB\(^2\) can occur at two equilibrium points \( \dot{\epsilon}_1 \) for \( k_01 = 6.05172 \times 10^{-4} \) and \( \dot{\epsilon}_2 \) for \( k_02 = 1.54738 \times 10^{-3} \), respectively.

3. The Approximate Analysis and Stability of Periodic Orbits

3.1. Computations of frequency, amplitude, and approximate analytical expression for periodic solution

In this section, by fourth-order harmonic balance method we wish to obtain a high accurate approximation of the periodic solution generated from Hopf bifurcation at equilibrium point \( \hat{\epsilon} \). The fourth-order harmonic balance explicit formula [Mees, 1981; Moiola et al., 1991; Moiola & Chen, 1993, 1996] is given by

\[
e(t) \approx \hat{\epsilon} + Re\left(\sum_{n=0}^{4} E_n \exp(i\omega_n t)\right),
\]

where \( E^0 = V_{01}^{\dot{\theta}} + V_{01}^\theta \), \( E^1 = V_{11} \dot{\theta} + V_{11}^\theta \), \( E^2 = V_{22} \ddot{\theta} + V_{22}^{\theta^2} \), \( E^3 = V_{33} \theta^3 + V_{33}^{\theta^3} \), \( E^4 = V_{44}^{\theta^4} \). \( \dot{\theta} \) and \( \theta \) denote the frequency and amplitude of periodic solution \( e(t) \), respectively, both of which are the solutions of the following equation:

\[
\lambda(\omega) = -1 - \theta^2 Z_1(\omega) - \theta^4 Z_2(\omega).
\]

The explicit expressions of \( V_{ij} \), \( Z_1(\omega) \) and \( Z_2(\omega) \) can be found in [Mees, 1981; Moiola et al., 1991; Moiola & Chen, 1993, 1996].

In order to compute \( \dot{\omega} \) and \( \dot{\theta} \) for Eq. (8), we separate the real and imaginary parts of Eq. (8) as follows:

\[
\begin{align*}
& Re\{\lambda(\omega)\} = -1 - \theta^2 Re\{Z_1(\omega)\} - \theta^4 Re\{Z_2(\omega)\} \\
& Im\{\lambda(\omega)\} = -\theta^2 Im\{Z_1(\omega)\} - \theta^4 Im\{Z_2(\omega)\}.
\end{align*}
\]

(9)

Suppose \( Z_2(\omega) \neq 0 \). By eliminating \( \theta^4 \) from (9), we obtain

\[
\begin{align*}
& Re\{\lambda(\omega)\} + Im\{Z_2(\omega)\} - Re\{Z_1(\omega)\}\lambda(\omega) = 0 \\
& Re\{Z_2(\omega)\} = -Re\{Z_1(\omega)\} Im\{Z_2(\omega)\}\theta^2.
\end{align*}
\]

(10)

We consider two cases.

**Case 1.** \( Re\{Z_2(\omega)\} Im\{Z_1(\omega)\} = Re\{Z_1(\omega)\} Im\{Z_2(\omega)\} \neq 0 \). In this case, (10) can be rewritten as

\[
\dot{\theta}^2 = Re\{\lambda(\omega)\} + Im\{Z_2(\omega)\} - Re\{Z_1(\omega)\}\lambda(\omega) Re\{Z_2(\omega)\} Im\{Z_1(\omega)\}
\]

\[
\pm h(\omega).
\]

(11)

Substituting (11) into the Eq. (9) yields

\[
\begin{align*}
& Re\{\lambda(\omega)\} = -1 - h(\omega) Re\{Z_1(\omega)\} \\
& - h^2(\omega) Re\{Z_2(\omega)\}
\end{align*}
\]

(12)

for \( Re\{Z_2(\omega)\} \neq 0 \), and

\[
\begin{align*}
& Im\{\lambda(\omega)\} = -h(\omega) Im\{Z_1(\omega)\} \\
& - h^2(\omega) Im\{Z_2(\omega)\}
\end{align*}
\]

(13)

for \( Im\{Z_2(\omega)\} \neq 0 \).

In order to find the roots \( \omega \) of Eq. (12) or Eq. (13), we firstly choose a \( k \) in the left small neighborhood of Hopf bifurcation parameter \( k_0 \), and
substitute $k$ into Eq. (12) or Eq. (13) to obtain numerical values of $\hat{\omega}$ sufficiently close to $\omega_0$. Then by substituting $\hat{\omega}$ into (11), the value of $\hat{\theta}$ will be computed. If the value of $\hat{\theta}$ is positive, the periodic solution emerging from Hopf bifurcation appears for $k < k_0$. If the value of $\hat{\theta}$ is negative, then the bifurcated periodic solution appears not for $k < k_0$ but for $k > k_0$. We need to choose a $k$ in the right small neighborhood of Hopf bifurcation parameter $k_0$ and compute ($\hat{\omega}$, $\hat{\theta}$).

**Case II.** $\text{Re}[Z_2(\omega)]\text{Im}[Z_1(\omega)] - \text{Re}[Z_1(\omega)]\text{Im}[Z_2(\omega)]=0$. In this case, (10) becomes

$$\text{Re}[\lambda(\omega)] + 1|\text{Im}[Z_2(\omega)]] - \text{Re}[Z_1(\omega)]\text{Im}[\lambda(\omega)] = 0. \quad (14)$$

Similarly, we numerically compute the values of $\hat{\omega}$ sufficiently close to $\omega_0$ from (14), and substitute $\hat{\omega}$ into (9) to obtain $\hat{\theta}$.

Following the procedure described above, we get the following results:

(I) The periodic orbit generated from HB at $\hat{\omega}_1$ appears in the right neighborhood of $k_0 = 6.05172 \times 10^{-3}$. For $k = 6.1045 \times 10^{-3}$, the fourth-order harmonic balance approximation expression of the periodic orbit with frequency

$$\dot{\omega} = 8.1068731623462 \times 10^{-2}$$

and amplitude

$$\hat{\theta} = 1.298375930657188 \times 10^{-7}$$

is given by

$$\epsilon(t) \approx \hat{\epsilon} + \text{Re} \left( \sum_{n=0}^{4} E^n \exp(i n \omega t) \right),$$

where $\hat{\epsilon} = (-3.1072073515 \times 10^{-6}, -3.9738278184 \times 10^{-7}, -0.00001397138896, -0.00153491273)^T$.

$E^0 = 10^{-7} \times \begin{pmatrix} -0.001378244627313 \\ -0.00267374533455 \\ -0.00081866958143 \\ -0.2187867694528839 \end{pmatrix}$

$E^1 = 10^{-7} \times \begin{pmatrix} -0.282277843257427 - 0.199006203393458i \\ 0.058826546219293 + 0.037503694716739i \\ 0.896125084883089 + 0.000000984037526i \\ 0.639531114456919 - 0.461923055035056i \end{pmatrix}$

$E^2 = 10^{-9} \times \begin{pmatrix} 0.151425449725114 - 0.134552850389603i \\ -0.052796538323410 - 0.018180657016606i \\ -0.302903844697538 + 0.339219531783535i \\ -0.46133743366638 + 0.408191526168601i \end{pmatrix}$

$E^3 = 10^{-11} \times \begin{pmatrix} 0.039716353296817 + 0.139511251979552i \\ 0.047818266031950 - 0.009187271976616i \\ -0.0484696075034954 - 0.275277050341816i \\ -0.16446984571708 - 0.258984462511374i \end{pmatrix}$

$E^4 = 10^{-13} \times \begin{pmatrix} -0.116036542786798 + 0.03214659214479i \\ -0.029448309065695 + 0.034077496390671i \\ 0.181657291018815 + 0.091919330614548i \\ 0.250753242302602 + 0.019605241552955i \end{pmatrix}$

(II) The periodic orbit generated from HB at $\hat{\omega}_2$ appears in the left neighborhood of $k_0 = 1.54738 \times 10^{-3}$. For $k = 1.547 \times 10^{-3}$, the fourth-order harmonic balance approximation expression of the periodic orbit

$1550093-6$
with frequency $\hat{\omega} = 6.1371869 \times 10^{-2}$ and amplitude $\hat{\theta} = 1.127697655889159 \times 10^{-6}$ is given by
\[
e(t) \approx \hat{e} + \text{Re} \left( \sum_{n=0}^{4} E^n \exp(i\hat{\omega}t) \right),
\]
where $\hat{e} = (-7.26348434 \times 10^{-7}, -3.708952782 \times 10^{-9}, -0.00003613998, -0.00134943716)^T$.

Periodic orbits calculated from our formulas (black curve) and by numerically solving differential equations (green “+”) are highly consistent with each other. Their graphs are shown in Figs. 1(a) and 1(b).

### 3.2. Detection of stability for periodic orbits

In [Jing et al., 2002], it was shown that the periodic orbit bifurcated from Hopf bifurcation is stable if one of Conditions (I) and (II) is satisfied: Condition (I). The argument of $\lambda(\omega)$, $\arg(\lambda(\omega))$, decreases as $\omega$ increases in the neighborhood of $(\hat{\omega}, \hat{\theta})$, and $\arg(\frac{d\lambda(\omega)}{d\omega})|_{(\hat{\omega}, \hat{\theta})} < 0$; Condition (II). The argument of $\lambda(\omega)$, $\arg(\lambda(\omega))$, increases as $\omega$ increases in the neighborhood of $(\hat{\omega}, \hat{\theta})$, and $\arg(\frac{d\lambda(\omega)}{d\omega})|_{(\hat{\omega}, \hat{\theta})} > 0$. Here, $L_2 = -1 - 2\theta^2 Z_1(\omega) - \theta^4 Z_2(\omega)$. $(\hat{\omega}, \hat{\theta})$ is the frequency and amplitude of the periodic solution $\lambda(\omega)$ along the increasing direction of $\omega$, and $\frac{d\lambda(\omega)}{d\omega}$ denotes the tangent vector of $L_2$ along the increasing direction of $\theta$. Note that
\[
\left. \frac{d\lambda(\omega)}{d\omega} \right|_{(\hat{\omega}, \hat{\theta})} \approx \frac{\hat{\lambda}(\hat{\omega}) - \lambda(\hat{\omega})}{\hat{\omega} - \omega_0},
\]
\[
\left. \frac{dL_2}{d(\theta)} \right|_{(\hat{\omega}, \hat{\theta})} \approx -Z_1(\hat{\omega}) - 2\theta^2 Z_2(\hat{\omega}),
\]
Therefore, the periodic orbit bifurcated from HB$_{1}$.

\[ \omega = 6.1371869 \times 10^{-2} \]

For convenience, we use the abbreviations: HB (Hopf bifurcation); PDB (period-doubling bifurcation); TR (torus bifurcation). We compute

\[ \arg(\lambda(\omega_1)) - \arg(\lambda(\omega_2)) = 1.680128924874680 \times 10^{-9} > 0 \]

and

\[ \arg \left( \frac{d\lambda(\omega)}{d\theta} \right) \bigg|_{\theta} = \frac{\lambda(\omega_1) - \lambda(\omega_2)}{-Z_1(\omega) - 2\theta^2 Z_2(\omega)} \approx -2.03928008314195 < 0. \]

Hence, the periodic orbit bifurcated from HB$_{2}$ at $k = 1.547 \times 10^{-3}$ is stable.

4. Numerical Simulations

In this section, we present numerical simulations to show bifurcations of periodic solutions, which emerge from Hopf bifurcation, and complex oscillations.

For convenience, we use the abbreviations: HB (Hopf bifurcation); PDB (period-doubling bifurcation); TR (torus bifurcation).

The bifurcation diagram of $k_f$ versus MAX $X. Wang et al.$

\[ \omega = 6.1371869 \times 10^{-2} \] and $\omega_2 = 6.1371870 \times 10^{-2}$,

where both $\omega_1$ and $\omega_2$ are in the small neighborhood of $\omega$ and sufficiently close to each other, thus we can determine the stability of periodic orbit by calculating $\frac{d\lambda(\omega)}{d\theta}$ and $-Z_1(\omega) - 2\theta^2 Z_2(\omega)$.

For the periodic orbit with frequency $\omega = 8.106873623462 \times 10^{-2}$ at $k = 6.1045 \times 10^{-4}$, we choose $\omega_1 = 8.106873623462 \times 10^{-2}$ and $\omega_2 = 8.10687317 \times 10^{-2}$, and have $\arg(\lambda(\omega_1)) - \arg(\lambda(\omega_2)) = 4.98084690719554 \times 10^{-10} > 0$,

\[ \arg \left( \frac{d\lambda(\omega)}{d\theta} \right) \bigg|_{\theta} = \frac{\lambda(\omega_1) - \lambda(\omega_2)}{-Z_1(\omega) - 2\theta^2 Z_2(\omega)} = -2.255624580755766 < 0. \]

Therefore, the periodic orbit bifurcated from HB$_{1}$ at $k = 6.1045 \times 10^{-4}$ is stable.
At a stable periodic orbit emerges from HB so that this equilibrium point loses its stability and a critical Hopf bifurcation HB occurs from HB. The equilibrium point is stable for \( k < k_f \) = 6.05172 \times 10^{-4}. The filled and open circles represent the stable and unstable equilibrium points, respectively. From Fig. 2, we can observe that the equilibrium point undergoes two supercritical Hopf bifurcations labeled as HB\(^1\) and HB\(^2\). The equilibrium point is stable for \( k < k_f \) = 6.05172 \times 10^{-4}. At \( k_f \), a supercritical Hopf bifurcation HB\(^1\) occurs, so that this equilibrium point loses its stability and a stable periodic orbit emerges from HB\(^1\). With a further increase in \( k_f \), the equilibrium point gains stability back through supercritical HB\(^2\) at \( k_f \) = 3.0 \times 10^{-2}. Figure 2 also shows the branch of the periodic solution generated from HB\(^2\). The filled and open circles indicate the stable and unstable periodic solutions, respectively. Table 2 shows the movement of Floquet multipliers along the branch of periodic orbit between \( k_f = 7.1906 \times 10^{-4} \) and \( k_f = 1.53081 \times 10^{-3} \). A stable periodic solution emerges from HB\(^2\) at \( k_f = 1.54643 \times 10^{-3} \) due to supercritical Hopf bifurcation HB\(^2\), the corresponding four Floquet multipliers are \( \{0.914603, 0.613985, 0.00021969\} \). As \( k_f \) decreases, a pair of complex conjugate multipliers 0.526870 \pm 0.836141i crosses the unit circle from the inside to the outside unit circle, so that a torus bifurcation TR occurs at \( k_f \) = 1.52493 \times 10^{-3}, and the periodic solution loses its stability. At \( k_f = 1.5248 \times 10^{-3} \), i.e. at high flow rate, we find a chaotic orbit with Lyapunov exponents \( \{0.0028469, 0.00068817, −3.3209\} \), which is shown in Fig. 3.

(e) Period-16 orbit for $k_f = 1.30864 \times 10^{-3}$.

(f) A chaotic orbit for $k_f = 1.309640802 \times 10^{-3}$.

Fig. 4. (Continued)
Figs. 1–6 suggest that the flow rate is presented in Fig. 6. Numerical simulations in When the reaction model, the flow rate $k_f$ of the BZ reaction model has been carefully and rigorously studied. Fourth-order harmonic balance method allowed us to obtain higher accurate predictions on frequencies and amplitudes for periodic solutions emerging from Hopf bifurcation. The explicit approximation expressions of the periodic solutions are also presented. Numerical simulations show several dynamical bifurcations emerging from Hopf bifurcation, including period-doubling bifurcation, chaotic attractor resulting from a cascade of period-doubling bifurcation, and torus bifurcation. For periodic solutions emerging from Hopf bifurcation, the periodic solutions are characterized by a pair of complex conjugate multipliers $0$ and $-1$, which results in the period-doubling bifurcation PDB. The unstable periodic solution has not regained its stability until PDB at $k_f = 1.30792 \times 10^{-3}$. When $k_f$ is slightly greater than $k_f^0$, the periodic solution undergoes a cascade of period-doubling bifurcation. Figures 4(a)–4(e) show the stable period-one orbit for $k_f = 1.3075 \times 10^{-3}$, period-two orbit for $k_f = 1.3085 \times 10^{-3}$, period-four orbit for $k_f = 1.3086 \times 10^{-3}$, period-eight orbit for $k_f = 1.30862 \times 10^{-3}$, and period-16 orbit for $k_f = 1.30864 \times 10^{-3}$, respectively. A chaotic orbit resulted from this cascade is presented in Fig. 4(f). Chaotic oscillation is observed in the region around $k_f \in [1.308640892 \times 10^{-3}, 1.52492 \times 10^{-3}]$. When $k_f$ continuously decreases from $k_f^0 = 1.30792 \times 10^{-3}$, a pair of complex conjugate multipliers $0.733855 \pm 0.665886i$ pass across the unit circle from the inside to the outside unit circle, so that the periodic solution encounters the torus bifurcation TR and loses its stability. Thus, a quasi-periodic orbit arises from this bifurcation. Figure 5 shows the projection of a quasi-periodic solution at $k_f = 7.156 \times 10^{-4}$. When $k_f = 7.1 \times 10^{-4}$, i.e., at low flow rate, we also find a chaotic attractor with Lyapunov exponents $\{0.004073, 0, -0.0006437, -2.2323\}$, which is presented in Fig. 6. Numerical simulations in Figs. 1–6 suggest that the flow rate $k_f$ has important effects on bifurcations and dynamics of BZ reaction model.

**Fig. 5.** The projection of a quasi-periodic trajectory and its time series for $k_f = 7.156 \times 10^{-4}$.

**Fig. 6.** The projection of a chaotic trajectory for $k_f = 7.1 \times 10^{-4}$.

**5. Conclusion**

Bifurcations of the BZ reaction model have been carefully and rigorously studied. Fourth-order harmonic balance method allowed us to obtain higher accurate predictions on frequencies and amplitudes for periodic solutions emerging from Hopf bifurcation. The explicit approximation expressions of the periodic solutions are also presented. Numerical simulations show several dynamical bifurcations emerging from Hopf bifurcation, including period-doubling bifurcation, chaotic attractor resulting from a cascade of period-doubling bifurcation, and torus bifurcation. We can observe chaotic orbits at both low and high flow rates, and the chaotic oscillations at high flow rate resulting from a cascade of period-doubling bifurcation.
of periodic-doubling bifurcation. Thus, we conclude that the flow rate $f_k$ does play an important role in the bifurcations of the model. All the results enrich our understanding of complex oscillations in BZ reaction model.
